1.2 Purpose

Aero-Metric, Inc. acquired high accuracy Light Detection and Ranging (LiDAR) data in the Area 3 region of eastern Kansas for the Kansas Department of Administration and Kansas Geological Survey in accordance with requirements specified to produce such dataset as outlined in contract ID 036574 and as defined by the National Digital Elevation Program (NDEP) and the American Society for Photogrammetry and Remote Sensing (ASPRS) and Other High Quality Digital Topography, as well as USGS National Geospatial Program Base LiDAR Specification, Version 13 (ILMF).

1.3 Project Locations

The project area includes three areas of Area 3 Kansas including: Bourbon, Brown, Buchanan, Butler, Cherokee, Crawford, Doniphan, Jackson, Leavenworth, Linn, Nemaha, Platte, Pottawatomie, Webaunsee, and Wyandotte counties. The Northeast area includes Brown, Doniphan, Jackson, Leavenworth, Nemaha, Pottawatomie, Webaunsee, and Wyandotte counties. The Southeast includes Cherokee, Crawford, Linn and Bourbon counties. The Butler area includes Butler County. Areas were defined and supplied by Kansas Department of Administration and includes approximately 9700 square miles for analysis.

1.4 Time Period

LiDAR data acquisition was performed January 13th, 2012 to April 17th, 2012. Fifty-four (54) missions were logged to cover the project area. See Items 3.3 a and b for a sketch of the acquisition passes and Section 7 contains each flight log.

1.5 Project Scope

To collect data over the approximately 9700 square miles of the project, aircraft were operated by; Keystone Aerial Surveys, Inc. and Aerometric Inc. utilizing Optech Gemini and Leica ALS70 airborne LiDAR systems. Data was collected at a nominal altitude of 2400 meters above ground to provide optimal data collection from the project area terrain.

2 GEODETIC CONTROL

QC surveys and control were completed between January 24th and April 21st, 2012.

2.1 Network Scope

Base horizontal control for the check point survey consisted of seventeen NGS CORS stations: **HBRK**, **ICT1**, **ICT3**, **KST5**, **KSU1**, **MOBT**, **MOCA**, **MOHV**, **MOID**, **MOMV**, **MONE**, **MOPL**, **MORK**, **MORM**, **MOSB**, **MOSV**, **ZKC1**: two NGS Order B stations: **K 56**, **P 340**; and three NGS First Order stations: **G 253**, **P 206**, **W 281**.

Horizontal control is referenced to the Universal Transverse Mercator (UTM) Coordinate System – Zone 14, based on the North American Datum of 1983 / High Accuracy Reference Network (HARN) (NAD83/HARN). Final coordinates are published in meters.

Base vertical control for the check point survey consisted of nine NGS First Order, Class 2 stations: **A 282**, **BELVUE**, **D 217**, **P 18**, **P 206**, **P 340**, **Q 210**, **W 281**, **Y 341**; twenty NGS Second Order stations: **801.25, 917**, **C 252 RESET**, **C 253**, **C 334**, **D 277**, **D 40**, **ELDORADO**, **G 251**, **G 253**, **H 274**, **K 334**, **K 56**, **M 325**, **P 215**, **Q 109**, **SKIRT RM 2**, **X 108**, **X 119**, **Z 231**; two NGS Third Order stations: **922 RESET**, **X 240 RESET**; and twelve NGS CORS stations: **HBRK**, **ICT3 KST5**, **KSU1**, **MOID**, **MOMV**, **MOPL**, **MORK**, **MORM**, **MOSB**, **MOSV**, **ZKC1** . The NGS stations **C 233 RESET**, **W 106**, and **X 274** were also observed, but not used as control due to large vertical misclosures. The NGS Model GEOID09 was applied to the derived ellipsoid heights to approximate the North American Vertical Datum of 1988.

Vertical control is based on the North American Vertical Datum of 1988 (NAVD88).

NGS recovery sheets are included in Section 9, Ground Control Survey Reports.

2.2 Network Computations

GPS measurements were done in two stages. Initial computations were done with LEICA Geo Office (LGO), version 4.0. LGO permits the conversion of raw satellite data collected by the receivers to a meaningful coordinate difference between points (baseline solutions). Once the baseline solutions were determined, they were input into the GeoSurv-GeoLab2 series of programs (Geolab version 2.4d). Due to the size and shape of the project, the data was split into three networks. Adjustments for each network were performed for analysis and quality closure holding the position and elevation one station fixed as follows:

3 LiDAR ACQUISITION AND PROCEDURES

3.1 Acquisition Time Period

LiDAR data acquisition and Airborne GPS control surveys were completed between January 13th, 2012 and April 17th, 2012. Fifty-four flight missions were required to cover the project areas. Some areas required re-flight due to unfavorable data acquisition conditions.

3.2 LiDAR Planning

The LiDAR data for this project was collected with Aerometric's Optech Gemini and Leica ALS70 and Keystone Aerial Survey's, Optech Gemini airborne LiDAR systems. All flight planning and flights were completed using Optech ALTM-Nav, version 2.1.25b (flight planning and LiDAR control software). Plan version 5.97 in .pln files.

Item 3.2 Acquisition details for the project acquisition flights.

Flying Height (Above Ground)	2400 m
Laser Pulse Rate	70 kHz
Mirror Scan Rate Frequency	29.5 Hz
Scan Angle (degrees)	18
Side Lap	30%
Ground Speed	160 kts
Nominal Point Spacing/meter	1.4

3.3 LiDAR Acquisition

A total of 54 flight missions were required to cover the project area. The missions were flown using the values in the chart above, Item 3.2. Images of the acquisition missions or flight lines in the three areas follow as Items 3.3 a and 3.3 b. Section 7 contains images of the flight log sheets.

Airborne GPS and IMU position and trajectory data of the LiDAR sensor were also acquired during the time of flight.

Missions were typically four to five hours long. Before take-off, the LiDAR system and the Airborne GPS and IMU system were initialized for a period of five minutes and in operation after landing for another five minutes. The missions acquired data according to the planned flight lines and included a minimum of one (usually two) cross flights. The cross flights were flown perpendicular to the planned flight lines and their data used in the in-situ calibration of the sensor.

3.4 LiDAR Trajectory Processing

4 QC SURVEYS

The check point survey was performed between January 24th and April 21st, 2012 using Rapid Static GPS techniques. The project includes three areas of varying size separated from one another. Ground survey personnel collected between 54 and 208 check points in each of these three areas. These points were collected in all terrain categories to assess vertical accuracies in each category.

The control stations mentioned above to support the Airborne GPS acquisition were also used to complete the QC surveys.

Items 4.0a b and c indicate an overview of check point locations.

5 FINAL LiDAR PROCESSING

5.1 ABGPS and IMU Processing

Airborne GPS

Applanix - POSGPS

Utilizing carrier phase ambiguity resolution on the fly (i.e., without initialization). The solution to sub-decimeter kinematic positioning without the operational constraint of static initialization as used in semi-kinematic or stop-and-go positioning was utilized for the airborne GPS post-processing.

TerraTec – TERRAPOS

TERRAPOS represents a state-of-the-art solution to Precise Point Positioning (PPP). TERRAPOS has been implemented to be fully compliant with data and products from leading international organizations, e.g. the International Earth Rotation and Reference Systems Service (IERS) and the International GNSS Service (IGS). TERRAPOS thus allows kinematic positioning with sub decimeter accuracy within the globally consistent and long-term stable reference frames maintained by the IERS.

In the PPP solution the carrier phase biases are estimated as real numbers (a so-called “float solution”). This confirms that the precision of the solution benefits from an increased data rate using an increased number of observations. However, this gain is ultimately limited by the time correlated errors in the observations that include but not limited to multipath and residual satellite clock errors. The data requires both dual-frequency code and carrier phase observations and uses respective ionosphere-free linear combinations. Doppler observations are also included in the computation for all kinematic profiles which assists the algorithm in the pre-processing to aid cycle slip detection and also helps to improve the position estimates.

Inertial Data

The post-processing of inertial and aiding sensor data (i.e. airborne GPS post processed data) is to compute an optimally blended navigation solution. The Kalman filter-based aided inertial navigation algorithm generates an accurate (in the sense of least-square error) navigation solution that will retain the best characteristics of the processed input data. An example of inertial/GPS sensor blending is the following: inertial data is smooth in the short term. However, a free-inertial navigation solution has errors that grow without bound with time. A GPS navigation solution exhibits short-term noise but has errors that are bounded. This optimally blended navigation solution will retain the best features of both, i.e. the blended navigation solution has errors that are smooth and bounded.

The resultant processing generates the following data:

- Position: Latitude, Longitude, Altitude
- Velocity: North, East, and Down components
- 3-axis attitude: roll, pitch, true heading
- Acceleration: x, y, z components
- Angular rates: x, y, z components

These procedures are utilized with the TerraTec TERRAPOS, version 2.0.4 (1851) software to determine the ABGPS trajectory. The blending of inertial data utilized only the Applanix software, version 4.4.

The airborne GPS and blending of inertial and GPS post-processing were completed in multiple steps.

The collected data was transferred by the field data collectors to the main computer. Data was saved under the project number and separated between LiDAR mission dates. Inside each mission date, a sub-directory was created with the aircraft's tail number and an A or B suffix was attached for the time of when the data was collected. Inside the tail number sub-directory, five sub-directories were also created EO, GPS, IMU, PROC, and RAW.

The aircraft raw data (IMU and GPS data combined) was run through a data extractor program. This separated the IMU and GPS data. In addition to the extracting of data, it provided the analyst the first statistics on the overall flight. The program was POSPac (POS post-processing PACkage), version 4.4.

Executing POSGPS program to derive accurate GPS positions for all flights:

TerraTech – TERRAPOS

The Applanix POSPac software requires ground base stations along with the airborne GPS data to compute the position and velocity of the sensor. Given the difficulties due to the ground stations as mentioned in Conditions Affecting Progress, a new processing technique was also employed to achieve the same superior accuracy as found with the traditional Applanix POSPac processing without the need of any base station support. This software used was TERRAPOS

The TERRAPOS procedure is to convert the binary structure of the GPS collected data to a Receiver Exchange format (RINEX) and is ingested into software and subsequently runs its advance and fully automated algorithms.

Once the data has been executed a graphical and a textual log is displayed. These values are inspected and accepted. An accepted accuracy would indicate an accuracy of 0.1m or less at a 95% of the entire mission. This accepted post-processed trajectory is relative to the ITRF, but the user could then relate the accepted trajectory positions to another Global Datum (e.g. NAD83). TERRAPOS has many fixed datums to pick from to relate it to their local reference datum. However, the reference for this project is the same as the processing it was completed in, and the accepted trajectories did not require a translation to another known datum.

When the processed trajectory data was accepted after quality control analysis, the combined solution is stored in a file format acceptable for the IMU post processor (i.e. POSProc).

Execute POSProc.

POSProc comprises a set of individual processing interface tools that execute and provide the following functions:

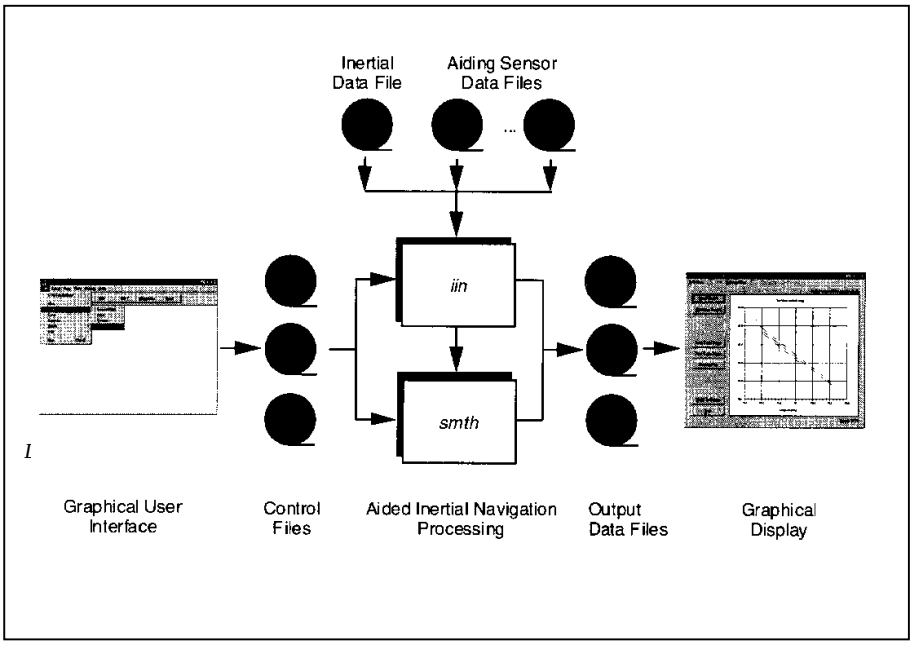

Diagram 3 shows the organization of these tools, and is a function of the POSProc processing components.

Integrated Inertial Navigation (iin) Module.

The name *iin* is a contraction of Integrated Inertial Navigation. *iin* reads inertial data and aiding data from data files specified in a processing environment file and computes the aided inertial navigation solution. The inertial data comes from a strapdown IMU. *iin* outputs the navigation data between start and end times at a data rate as specified in the environment file. *iin* also outputs Kalman filter data for analysis of estimation error statistics and smoother data that the smoothing program *smth* uses to improve the navigation solution accuracy.[3]

iin implements a full strapdown inertial navigator that solves Newton's equation of motion on the earth using inertial data from a strapdown IMU. The inertial navigator implements coning and sculling compensation to handle potential problems caused by vibration of the IMU. [3]

Smoother Module (smth).

smth is a companion processing module to *iin*. *smth* is comprised of two individual functions that run in sequence. *smth* first runs the *smoother function* and then runs the *navigation correction function*.[3]

The *smth* smoother function performs backwards-in-time processing of the forwards-in-time blended navigation solution and Kalman filter data generated by *iin* to compute smoothed error estimates. *smth* implements a modified Bryson-Frazier smoothing algorithm specifically designed for use with the *iin* Kalman filter. The resulting smoothed strapdown navigator error estimates at a given time point are the optimal estimates based on all input data before and after the given time point. In this sense, *smth* makes use of all available information in the input data. *smth* writes the smoothed error estimates and their RMS estimation errors to output data files. [3]

The *smth* navigation correction function implements a feedforward error correction mechanism similar to that in the *iin* strapdown navigation solution using the smoothed strapdown navigation errors. s*mth* reads in the smoothed error estimates and with these, corrects the strapdown navigation data. The resulting navigation solution is called a Best Estimate of Trajectory (BET), and is the best obtainable estimate of vehicle trajectory with the available inertial and aiding sensor data. [3]

The above mentioned modules provide the analyst the following statistics to ensure that the most optimal solution was achieved: a log of the *iin* processing, the Kalman filter Measurement Residuals, Smoothed RMS Estimation Errors, and Smoothed Sensor Errors and RMS.

5.2 LiDAR "Point Cloud" Processing

The ABGPS/IMU post processed data along with the LiDAR raw measurements were processed using Optech Incorporated's ASDA software. This software was used to match the raw LiDAR measurements with the computed ABGPS/IMU positions and attitudes of the LiDAR sensor. The result was a "point cloud" of LiDAR measured points referenced to the ground control system.

5.3 LiDAR CALIBRATION

Introduction

The purpose of the LiDAR system calibration is to refine the system parameters in order for the post-processing software to produce a "point cloud" that best fits the actual ground.

The following report outlines the calibration techniques employed for this project.

Calibration Procedures

All Companies involved in collection routinely performs two types of calibrations on its airborne LiDAR system. The first calibration, system calibration, is performed whenever the LiDAR system is installed in the aircraft. This calibration is performed to define the system parameters affected by the physical misalignment of the system versus aircraft. The second calibration, in-situ calibration, is performed for each mission using that missions data. This calibration is performed to refine the system parameters that are affected by the on site conditions as needed.

System Calibration

The system calibration is performed whenever the LiDAR system is installed in the aircraft. This calibration is performed to define the system parameters affected by the physical misalignment of the system versus aircraft. The main system parameters that are affected are the heading, pitch, roll, and mirror scale.

The system calibration is performed by collecting data over a known test site that incorporates a flat surface and a large, flat roofed building. A ground survey is completed to define the flat surface and the building corners. The processed LiDAR data and ground survey data is input into TerraSolid's TerraMatch software to determine the systematic errors. The system parameters are then corrected according to the determined errors and used in the processing of future LiDAR acquisition missions

In-situ Calibration

The in-situ calibration is performed as needed using the mission's data. This calibration is performed to refine the system parameters that are affected by the on site conditions.

For each mission, LiDAR data for at least one cross flight is acquired over the mission's acquisition site. The processed data of the cross flight is compared to the perpendicular flight lines using either the Optech proprietary software or TerraSolid's TerraMatch software to determine if any systematic errors are present. In this calibration, the data of individual flight lines are compared against each other and their systematic errors are corrected in the final processed data.

5.4 LiDAR Processing

The LAS files were then imported, verified, and parsed into manageable, tiled grids using GeoCue version 2011.1.20.1. GeoCue allows for ease of data management and process tracking.

The first step after the data has been processed and calibrated is to perform a relative accuracy assessment on the flightline to flightline comparisons and also a data density test prior any further processing.

In addition to the relative accuracy assessment, Aerometric also reviews a few tiles to ensure that the desired point density has been met. Aerometric utilizes an in- house proprietary software to complete this task. Initially a grid is placed according to the version 12 specification that is based on the nominal post spacing. Point density is analyzed and the result indicates the density of the sampled tiles. The latest USGS specification, version 13, modifies the requirement allowing up to 2 times the nominal post spacing. Our data evaluation acknowledges this change.

Once both the accuracy between swaths and data density is accepted an automated classification algorithm is performed using TerraSolid's TerraScan, version 012.010. This will produce the majority of the bare-earth datasets.

The remainder of the data was classified using manual classification techniques. The majority of the manual editing involved changing points initially misclassified as ground (class 2) to unclassified (class 1). Erroneous low points, high points, including clouds are classified to class 7.

5.5 Check Point Validation

The data was then verified against ground control data. TerraScan computes the vertical differences between the surveyed elevation of ground control points and the LiDAR derived elevations at these points.

A report listing the differences and common statistics was created and can be found in Section 9, of this report.

5.6 LiDAR Data Delivery

Raw point cloud data supplied is in the following format:

- LAS, version 1.2
- GPS times adjusted to GPS Absolute
- Full swaths and delivered as 1 file per swath which did not exceed 2 gigabytes.

Classified point cloud data is also being supplied using the following criteria.

- LAS, version 1.2 in 5000 meter grid
- GPS times adjusted to GPS Absolute
- Classification scheme:
  - 1 – Processed, but unclassified
  - 2 – Bare Earth, Ground
  - 7 – Noise
  - 9 – Water
  - 10 – Ignored Ground (Breakline proximity)
  - 11 – Withheld
  - 17 – Overlap – unclassified
  - 18 – Overlap – Bare-Earth
  - 23 – Overlap – noise
  - 24 – Overlap – water
  - 25 – Overlap – Ignored Ground

Bare earth hydro-flattened 1 meter DEMs were created using TerraModeler (TerraSolid Ltd.). The ASCII grids were then imported into ARC and translated to raster format and placed in a geo-database DEM feature dataset.

First return 1 meter DEM images were created using GeoCue. They are geo-referenced and converted to IMG format.

Break lines polygon are first collected in a Microstation environment using the project specifications. They are checked for QC/QA. Upon acceptance the breaklines, either polygons or lines, are translated into ARC and imported to the final geo-database as separate features.

6 CONCLUSION

Sound procedures and use of new technology ensure this project data will serve the Kansas Department of Administration and Kansas Geological Survey and all users requiring the provided LiDAR derivative products for the project areas in eastern Kansas well into the future. Although this project presented challenges to equipment and personnel, the results are accurate and reliable.

NOTE: All confidence regions were computed using the following factors:

Variance factor used = 1.0000
3-D expansion factor = 2.7955

Note that, for relative confidence regions, precisions are computed from the ratio of the major semi-axis and the spatial distance between the two stations.
